Linear regression is often used to compare two methods which each other. The slope, the intercept and the correlation are then the parameters for the goodness of fit.

By using unweighed linear regression it is often forgotten that it is assumed that the x-value is errorfree, which is often not true. This program takes the error in both observation in account.

The correlation coefficient has the disadvantage that it is dependent of the range and the quantity of observations.

There are three possibilities to start the program:

- 1) Using it unweighed by entering SDEV x= SDEV y when asked.
- 2) By doing the test multiphorous. The program DUPLO, TRIPLO or higher should be used then. The choice of the program depends on how many times one sample is tested in one method. The standarddeviation is calculated from these data and the mean standarddeviation is used to determine the weighing factor λ . It is also possible to enter the standarddeviation calculated for 3) by pressing "B".
- 3) By testing samples independently and determining the intraassay standarddeviation. The program MEAN should be used then, which gives the possibility to enter the standarddeviation of x and y. This last method is the most recommended one.

The meaning of the results.

- 1) SDEV X and SDEV Y are the calculated standarddeviations from the multiphorous data.
- 2) Lambda (λ) is the weighing factor which is determined by the variances of method x and y, who are calculated at 1). (8)
- 3) $S_{y.y}$, $S_{x.x}$, $S_{x.y}$ are the covariances (1)(2)(3).
- 4) Correlationcoefficient R. (4)
- 5) Student's t-distribution is used to test if the observed correlation is significantly different from zero.
- 6) DF is degrees of freedom. (5)

- 6) MEAN X and MEAN Y are the mean of all entered x and y data.
- 7) N is the number of groups of samples
- 8) Y/X is the forced slope of the line through the origin.
- 9) S_{yx}^2 is the residual variance, which is a quantity to see how good the pairs of observations are fitted to the regressionline. This quantity is used to calculate the standarddeviation of the slope and the intercept and the experimental deviations. (11)
- 10) aG and Bg are the weighed slope and intercept (6)(7)
- 11) a and b are the unweighed slope and intercept, which are derived from the assumption that x is without error. (9)(10)
- 12) $s_{\text{H..}}$ is the standarddeviation of the slope and intercept. (12)
- 13) $S_x \text{EXP}$, $S_y \text{EXP}$ are the experimental standarddeviations around the regressionline. These quantities are also estimated in the multiphorous data entered. (13)
- 14) With aid of the F-test of Fisher we can test whether the standarddeviation derived experimentelly and from the data are significantly different from eachother or not. If so then there is a systematic error between the x and y method. (14)
If $F < 1.0$ you have to perform $1/X$ and to change the degrees of freedom $n-2$ and $k-1$, to read an upper percentage point table.

n = number of samples used for S_x^2 , S_y^2 . (Df given at t-test is already $n-2$)

k = number of samples used for S_x^2 , S_y^2 . (When program TRIPLO is used $k=3$, when program sixfold $k=6$)

(..) refers to the formulas at page 2.
